JBScreen Thermofluor FUNDAMENT HTS
TSA for protein stability

<table>
<thead>
<tr>
<th>Cat. No.</th>
<th>Amount</th>
</tr>
</thead>
</table>
| CS-332   | 93 solutions (0.5 ml each)  
          | Control Protein (1.0 ml) |

For in vitro use only. 
Quality guaranteed for 12 months. 
Store at 4 °C.

**Application**

Screen for thermal stability of proteins as a function of the FUNDAMENTAL variables pH and ionic strength without interference from SPECIFIC (undesired buffer-change and additive) effects.

**Additionally required (not in the kit):**

- suitable PCR plates
- JBS Thermofluor Dye (Cat.No. X-TD-70)
- Standard real-time PCR machine with excitation filter at 483 nm and emission at 568 nm
- Statistical software packages for data analysis such as Origin (http://www.originlab.com/), Grafit (http://www.erithacus.com/grafit/) or Graphpad (http://www.graphpad.com/)

**The concept of FUNDAMENTAL and SPECIFIC variables affecting protein stability in vitro**

Protein stability in vitro - greatly dependent on the protein’s aqueous buffered environment - is crucial for protein purification, characterization and crystallization. Commonly, this environment is considered to be determined by i) pH ii) ionic strength and iii) additives. This however, has the general weakness of lacking mutual exclusivity since pH, ionic strength and additives are interdependent variables. An environment of identical pH 7.5 may, for example, be obtained by 100 mM TRIS/HCl or 50 mM HEPES/NaOH buffer while ionic strength (100 mM vs. 50 mM buffer) and additives (buffer molecules, Na+ vs. Cl-) make up significantly different conditions with unpredictable effect on protein stability - and potentially overlaying/masking the pure pH-effect.

Therefore, the JBScreen Thermofluor FUNDAMENT and the JBScreen Thermofluor SPECIFIC base on an alternative approach in which protein environment is categorized into

1. FUNDAMENTAL factors that influence the whole protein molecule and
2. SPECIFIC factors that affect energetically important hot spots on the protein.

FUNDAMENTAL factors are the proton (H+) concentration (i.e. the pH) together with the ionic strength (i.e. the concentration of all electrolytes). These affect a plethora of sites on the entire protein thus altering its fundamental intra- and intermolecular interactions such as coulombic, electrostatic and hydrophobic interactions, salt bridges, hydrogen bonds, and Van der Waals forces.

SPECIFIC factors are additives that, in contrast, affect only one...a few distinct but energetically important sites on the protein (e.g. active site, catalytic cleft, dimerization interface) and include basically any small molecule interacting with the protein such as substrates and their analogs, cations, anions, and many more.

The JBScreen Thermofluor FUNDAMENT and the JBScreen Thermofluor SPECIFIC are designed to eliminate the undesired overlay of simultaneous screening of interdependent variables. They strictly categorize stability screening of proteins into

- fundamental (pH and ionic strength) and
- specific (all other) variables to the maximum possible extent.
The JBScreen Thermofluor FUNDAMENT for protein stability

A common reporter for protein stability is its melting temperature (Tm) that can easily be determined by TSA (thermal shift assay, Fig. 1). The higher the Tm, the higher is the thermostability of the protein in that specific environment. Therefore, optimization of protein environments became a routine approach to gain stability, particularly prior protein crystallization: It was shown that Tm-increasing environments directly correlate with increased likelihood of protein crystals that yield good diffraction data for structure determination [1, 2].

The JBScreen Thermofluor FUNDAMENT uses the TSA methodology for identification of the fundamental variables for protein stability. It is composed of two different broad-range buffer systems (“Super-Buffers”) covering pH 4.0 to 10.0 as a function of ionic strength (0 to 1M NaCl). The designed FUNDAMENT formulation therefore allows screening of pH and ionic strength while maintaining the chemical nature of the protein’s environment (Fig.2).

Fig. 1: TSA (Thermal shift assay) is a rapid and simple denaturation technique that monitors the unfolding of a protein in a temperature-dependent manner. At low temperatures, the protein is properly folded. As temperature increases, the protein is gradually denatured, enabling a present fluorophore to interact with the protein’s exposed hydrophobic patches. This results in a fluorescence increase (signal) until the protein is unfolded. From the resulting sigmoidal melting curve the melting temperature Tm can be extracted [3].
Experimental Protocol

A pre-assay for determination of the optimal target protein and dye concentration is recommended. Screening should be performed in triplicate, background plates (containing buffer without protein) in duplicate.

Apply 15 µl screening solution in 25 µl final assay volume and 2.5 µl control protein in wells A1-A9. Use any real-time thermocycler (excitation 483 nm / emission 568 nm) for fluorescent measurements; recommended parameters:
- 2 min initial incubation at 25 °C
- melting temperature range from 25 °C to 99 °C in 1 °C/min

Fig. 2: The JBScreen Thermofluor FUNDAMENT is designed for TSA in a 96-well PCR plate with a final volume of 25 µl per well: 15 µl screening solution + protein sample and fluorescent dye to a maximum volume of 10 µl. This dilution yields a final buffer concentration of 100 mM and a final NaCl concentration of 0, 50, 125, 250, 500 and 1000 mM from columns 1-6 and 7-12, respectively.

A1-A9 allow for control assay with the supplied control protein (CP) in control buffer; A10-A12 are empty wells for the reference assay with target protein (TP) in original buffer.

Super Buffer 1 = CHC buffer, produced by mixing Citric acid:HEPES:CHES in the molar ratios 2:3:4;
Super Buffer 2 = MIB buffer, produced by mixing Malonic acid:Imidazole:Boric acid in the molar ratios 2:3:3.
Data Analysis

Export the raw fluorescence data of the assay plate (AP) triplicates and the background plate (BP) duplicates. Calculate the average of the AP triplicates and subtract the average of the BP duplicates to obtain the averaged melting curve (AMC) for every corresponding well:

\[ \text{AMC} = \frac{AP_1 + AP_2 + AP_3}{3} - \frac{BP_1 + BP_2}{2} \]

Use the Boltzmann sigmoid for AMC model fitting [2]. The slope at its inflection point corresponds to the protein melting temperature in each of the different well conditions.

**Data Analysis of the control assay**

The control assay shows the pure pH effect on the thermostability of the CP independent of the chemical buffer composition. The control assay is performed in each plate in wells A1-A9.
